

**When aluminium science
and technology become
recre@ting**

What is aluMATTER?

- Modular interactive and innovative web-based learning resources about **aluminium materials science and technologies**.
- Used as distant **self-learning material** and **complementary learning material** in vocational training programs and in higher education.
- A package of **9 modules** covering the main aspects of aluminium materials science and fabrication technologies will be completed within the next 2 years.

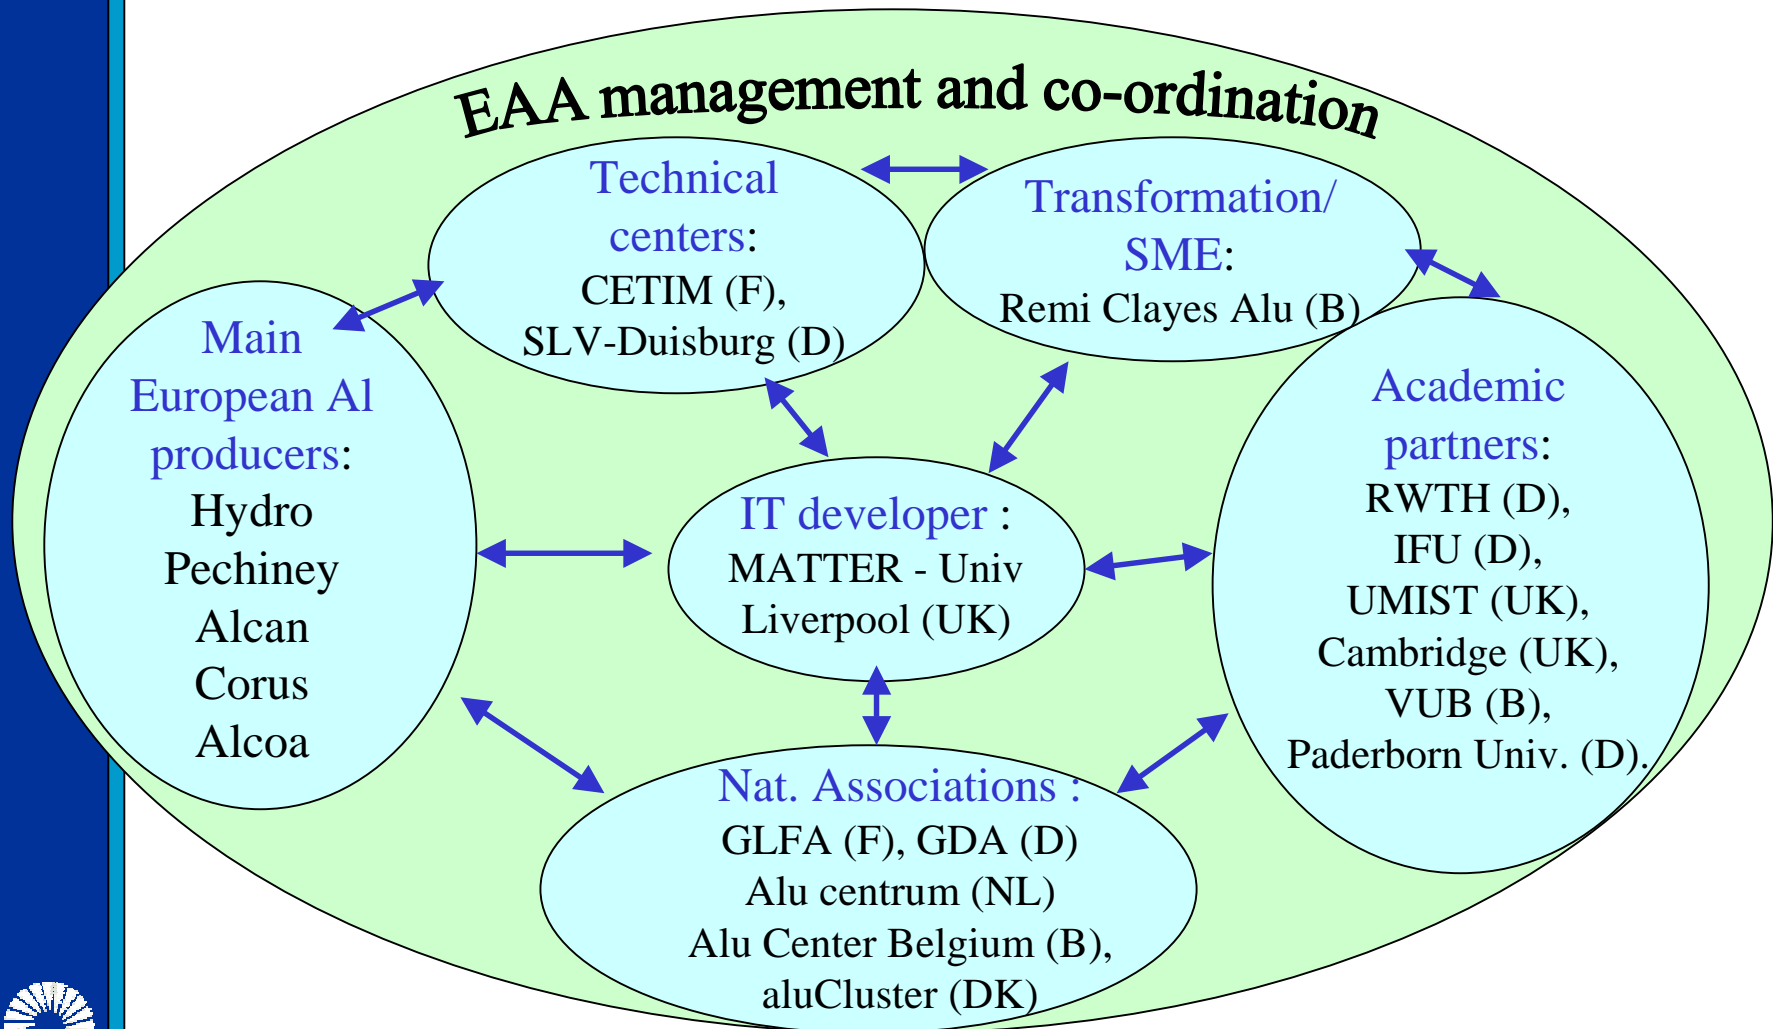

9 modules & 3 entry points

Leonardo da Vinci project 2003-2005

- Budget of 1 M€ on 3- years covered for about 50% by the European Commission
- The European Aluminium Industry thanks the European Commission for this Leonardo da Vinci funding
- **Why a Leonardo funding?**
 - Expertise in fabrication technology often outside the Aluminium Industry (Technical centers, University, etc.)
 - Needs for establishing a large network for proper development, translation and dissemination towards students and SME's
 - Establishing a well-balanced partnership

Consortium of 21 partners

How is it developed?

- Small expert working groups (Industrial experts and Academics) in charge of **storyboarding**
- Storyboards developed under guidance and supervision of the MATTER group who is in charge of the programming and encoding work
(see <http://www.matter.org.uk>)

- MATTER = leading providers of computer- and web-based learning software for materials science, engineering and related disciplines.
- Primarily developed in **English**, but provision is already made to translate into **French, German and Dutch**.

What behind a module?

- Each module composed of
 - about 80-100 computer screens
 - including learning outcomes, pre-requisites, interactive animations, multiple-choice questions, virtual experiments and simulations
 - corresponding to about 6-8 hours of traditional lessons
- Web structure designed to allow the content to be accessed via three entry points:
 - Products/applications,
 - Materials Science
 - Processing

[Send feedback to EAA](#)

Welcome to **aluMATTER** - a freely-accessible website that aims to provide **innovative** and **interactive** e-learning tools for aluminium science and technology.

FREE
Searchable Database

The site currently contains three 'modules' covering some of the more fundamental aspects of aluminium metallurgy:

- ▶ [Strengthening Mechanisms](#)
- ▶ [Softening Mechanisms](#) **NEW**
- ▶ [Anisotropy](#) **NEW**

In 2002, aluMATTER successfully bid for funding from the Leonardo da Vinci programme of the European Union to develop a further 6 modules: "Mechanical Properties", "Functional Applications", "Machining", "Forming", "Joining" and "Corrosion & Surface Properties".

Solute Hardening Overview

The substitution of aluminium by solute atoms results in lattice distortions and a local increase in the energy of the crystal lattice.

Dislocations passing through such regions also experience an increase in energy, and hence additional work must be done to move them - i.e. the yield stress of the metal increases.

For successful strengthening, alloy additions must satisfy 2 criteria:

1. high RT solid solubility;
2. atomic misfit to create local compressive or tensile strains.

Drag the foreign atoms onto Al atoms in the lattice and note the strain effects.

Example of a virtual experiment: hardness testing

Introduction

Rolling & Measurement

Annealing

Grain Size Measurement

Hardness Testing

Results

Introduction

In this experiment, you are going to check the validity of the Hall-Petch relationship for an Al-4.5%Mg alloy.

$$\sigma_y = \sigma_0 + kd^{1/2}$$

Firstly we need to prepare samples with a range of different grain sizes, d . We'll do this by deforming (rolling) a plate by different amounts, cutting samples at each stage. We'll then anneal the samples to fully recrystallise them. Heavily deformed samples should recrystallise to give a finer grain size.

After measuring the grain sizes, you will do Vickers hardness measurements on each, and convert hardness to yield stress, σ_y values.

By plotting σ_y versus $d^{1/2}$, we should expect to obtain a straight line of gradient k and intercept σ_0 .

Before starting, copy or print out the datasheet below. Then click on the forward arrow to proceed.
